

Inferring a common rate

```
import os

if "KERAS_BACKEND" not in os.environ:
    # set this to "torch", "tensorflow", or "jax"
    os.environ["KERAS_BACKEND"] = "jax"

import matplotlib.pyplot as plt
import numpy as np
import bayesflow as bf
```

```
INFO:bayesflow:Using backend 'jax'
```

In this section we will estimate a common binomial rate that produces two binomial processes according to the following model:

$$\begin{aligned} k_1 &\sim \text{Binomial}(\theta, n_1) \\ k_2 &\sim \text{Binomial}(\theta, n_2) \\ \theta &\sim \text{Beta}(1, 1). \end{aligned} \tag{1}$$

Simulator

The individual components of the model are very similar to a combination of the previous two examples: Now we have one binomial proportion but two binomial outcomes.

```
def context():
    return dict(n=np.random.randint(1, 101, size=2))

def prior():
    return dict(theta=np.random.beta(a=1, b=1))
```

```

def likelihood(n, theta):
    return dict(k=np.random.binomial(n=n, p=theta))

simulator=bf.make_simulator([context, prior, likelihood])

```

Approximator

```

adapter = (
    bf.Adapter()
    .constrain("theta", lower=0, upper=1)
    .rename("theta", "inference_variables")
    .concatenate(["k", "n"], into="inference_conditions")
)

```

```

workflow=bf.BasicWorkflow(
    simulator=simulator,
    adapter=adapter,
    inference_network=bf.networks.CouplingFlow()
)

```

Training

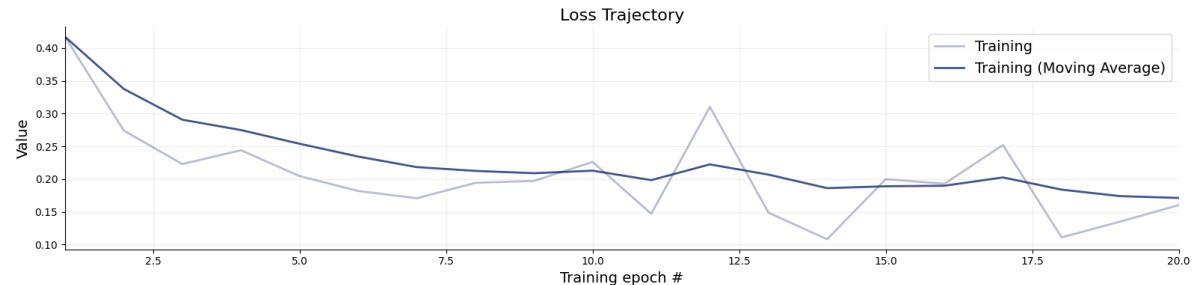

```
history=workflow.fit_online(epochs=20, batch_size=512)
```

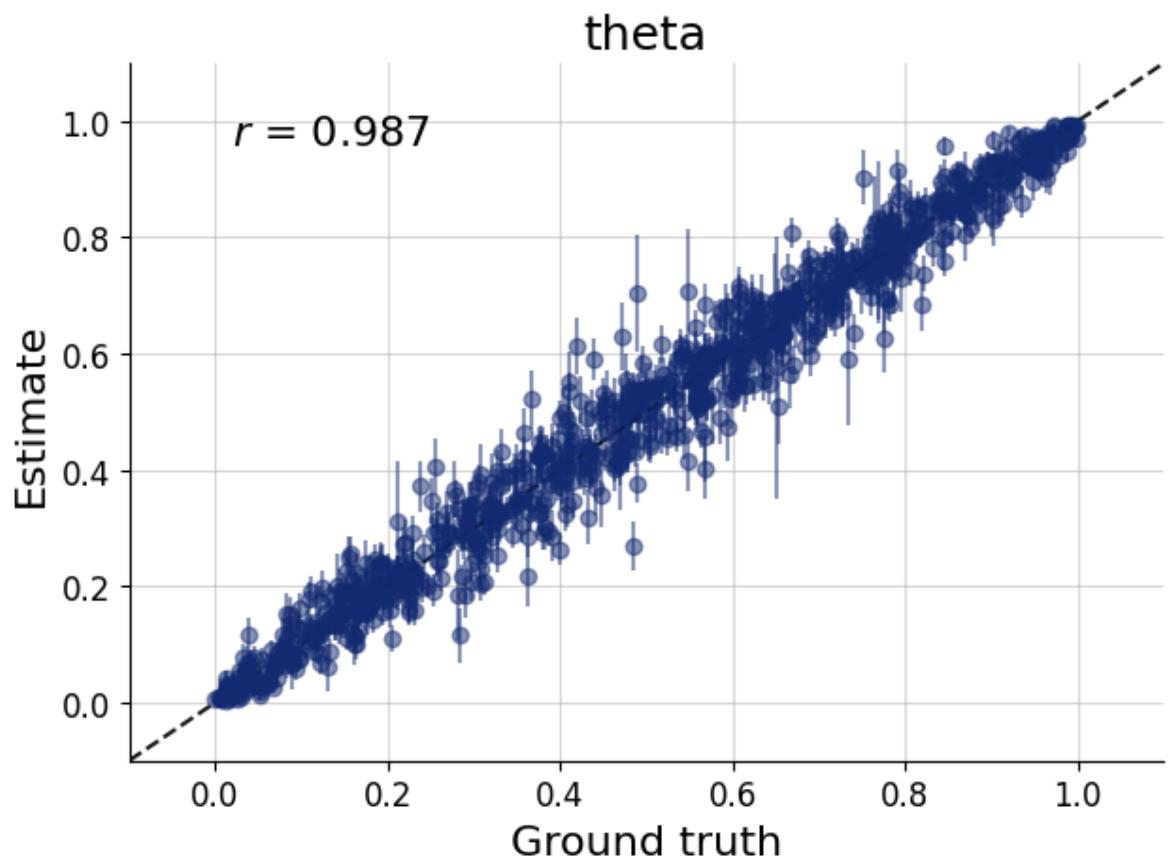

Validation

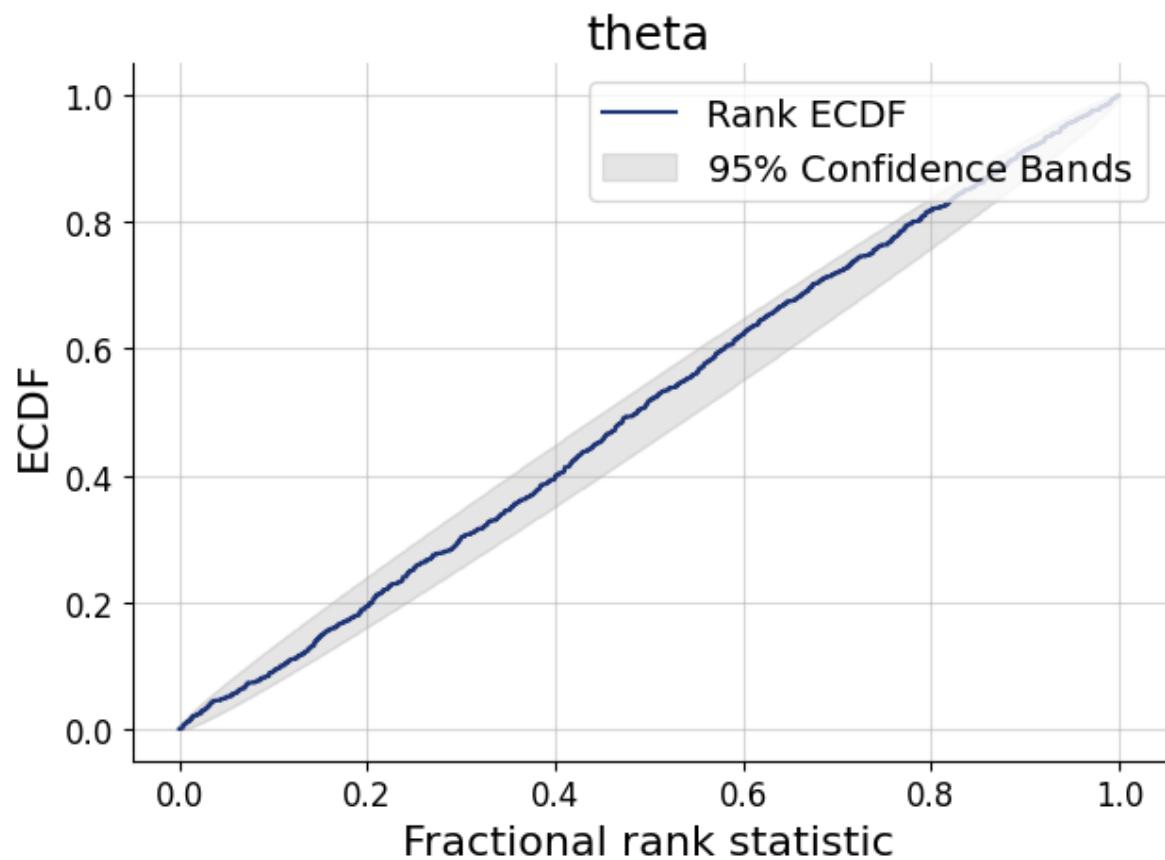

```

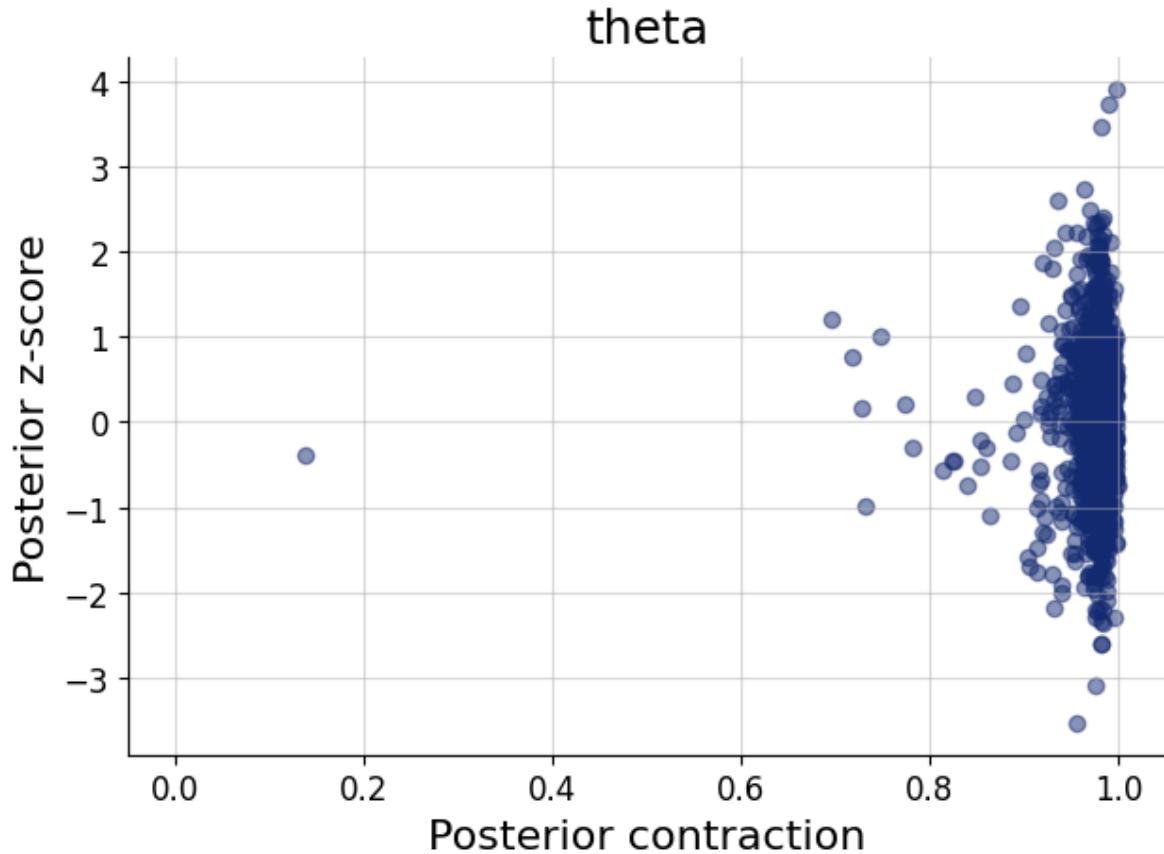

test_data=simulator.sample(1000)
figs=workflow.plot_default_diagnostics(test_data=test_data, num_samples=500)

```

Inference

Now that we trained the network we can use it for inference. We are given four data sets by Lee & Wagenmakers (2013):

1. $k_1 = 14, k_2 = 16, n_1 = n_2 = 20$
2. $k_1 = 0, k_2 = 10, n_1 = n_2 = 10$
3. $k_1 = 7, k_2 = 3, n_1 = n_2 = 10$
4. $k_1 = k_2 = 5, n_1 = n_2 = 10$

The advantage of BayesFlow is that we can obtain the samples for these three independent data sets *at once*. We simply define an array of data sets that are passed to the inference network.

```
inference_data=dict(
    k = np.array([[14, 16], [0, 10], [7, 3], [5, 5]]),
```

```

    n = np.array([[20, 20], [10, 10], [10, 10], [10, 10]])
)

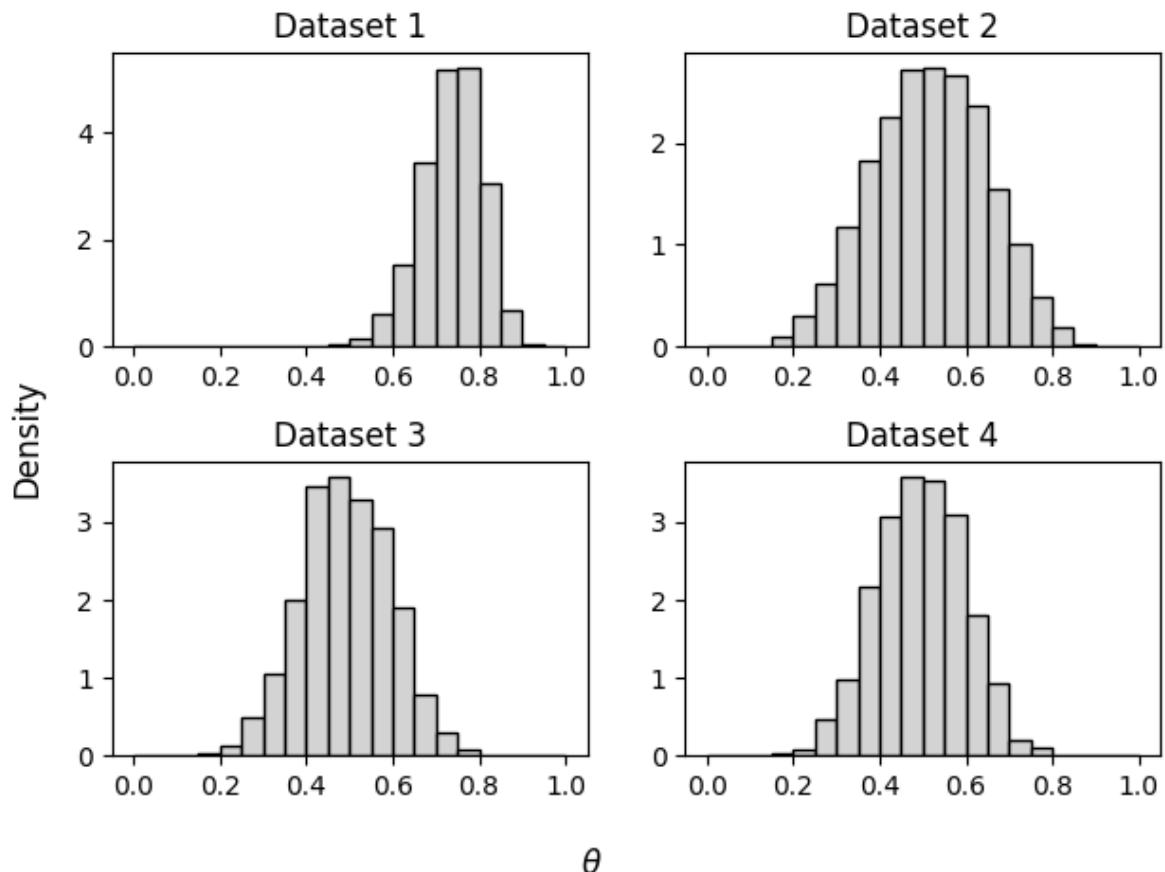

samples=workflow.sample(num_samples=2000, conditions=inference_data)

fig, axs = plt.subplots(nrows=2, ncols=2)
axs=axs.flatten()

for i, ax in enumerate(axs):
    ax.set_title("Dataset " + str(i + 1))
    ax.hist(samples["theta"][i],
            density=True, color="lightgray", edgecolor="black", bins=np.arange(0, 1.05, 0.05))

fig.supxlabel(r"\theta")
fig.supylabel("Density")
fig.tight_layout()

```
